Keywords

Scrofuloderma; Hydradenitis suppurativa; Differential diagnosis

Clinical Image

27 -year-old male patient admitted to our out-patient clinic with depressed scarring granulomatous pustuler lesion on the face, beard-region (Figure 1). He described hydradenitis suppurativa lesions axillary and inguinal folds and treated with antibiotics for 2 years but moderate improvement. The disease going on with new pustules (Figure 2). We suspected of scrofuloderma and sent our patient to tuberculosis fight center. PPD was 15 mm and lung graph was normal. The patient treated combined therapy for skin tuberculosis for 6 months. Scrofuloderma must be thought in the differential diagnosis of hydradenitis suppurativa [1-3].
